IMPLEMENTATION CASE STUDY - BUILT BEFORE CURRENT LLM TOOLS

Yardi-Argus Model Bridge: Turning GL Actuals and Argus Forecasts Into One Asset-Management Model

Built a reusable Excel and Power Query architecture that transformed Yardi GL exports and Argus cash-flow forecasts into a single monthly actual-to-forecast model for CRE asset management. The system improved short-to-medium term distribution forecasting, supported longer-term IRR time-series analysis, and let asset managers drill into structured GL detail without waiting for routine accounting pulls.

ROLE
Designed, built, maintained, documented, and updated the model workflow

USERS
4+ asset-management users; SVP, CFO, executive team; summarized externally for JV partners

SCOPE
20 investor-facing AM models in 6 months; 30 in 12 months; GL transformation usable across 70+ portfolio properties

STACK
Excel, Power Query M, Power Pivot/Data Model, Yardi GL exports, Argus cash-flow exports

2-3 min
GL PERIOD + ARGUS FORECAST REFRESH VS. 80-90 MINUTES MANUALLY

20
INVESTOR-FACING AM MODELS IN 6 MONTHS

30
INVESTOR-FACING AM MODELS IN 12 MONTHS

70+
PORTFOLIO PROPERTIES AVAILABLE FOR GL TRANSFORMATION

~$800K
Q4 2025 CAPITAL-CALL DECISION SUPPORT

SCOPE CLARITY - THREE RELATED USE CASES

1. Yardi GL-only transformation.
Raw GL exports became a normalized pivot-table output for structured actuals review. This pattern could be used across 70+ portfolio properties as needed.

2. Yardi + Argus integrated model.
Historical actuals, Argus forecasts, debt, cash, and net working capital logic landed in one drill-down workbook.

3. Investor-facing summary model.
Quarterly reporting used summary Excel outputs, not the full GL-detail drill-down, because the detailed workbook was too sensitive to share externally.

Net working capital means short-term balance-sheet accounts such as receivables, payables, prepaids, and accruals that affect actual cash available for distributions or capital calls.

BEFORE > AFTER

BEFORE — 6 STEPS

1. **Pull disconnected exports**
   Yardi actuals, Argus forecasts, debt, and cash details lived in separate surfaces.
2. **Map accounts by hand**
   Argus forecast rows did not line up cleanly with canonical accounting GL categories.
3. **Ask accounting for detail**
   Spike or outlier questions often required follow-up pulls instead of immediate drill-down.
4. **Refresh forecasts manually**
   A GL-period plus Argus refresh could take roughly 80-90 minutes when rebuilt manually.
5. **Model cash separately**
   Cash, debt, and working-capital timing were hard to incorporate consistently.
6. **Summarize manually**
   Partner-facing outputs depended on manually assembled support.

MANUAL REFRESH **80-90 min**

AFTER — 4 STEPS

1. **Drop exports into folders**
   New Yardi GL files and Argus exports land in known locations.
2. **Refresh Power Query**
   Folder ingestion, cleanup, sign normalization, mapping, and appends run after setup.
3. **Review model controls**
   Cash tie-outs, period filters, and variance checks gate usage.
4. **Use one model output**
   AM, leadership, and JV summaries start from the same actual-to-forecast view.

CONFIGURED REFRESH **2-3 min**

SUPPORTING EXAMPLE

The most experienced model user could build a 6-12 month cash reforecast in roughly 10-15 minutes vs. about 2.5 hours manually.

MODEL OUTPUT - ACTUALS TO FORECAST IN ONE VIEW

The working model compressed historical accounting detail and forward Argus forecasts into a model-readable monthly cash-flow view. The red dotted line in the screenshot separates Yardi GL actual results on the left from future Argus forecast periods on the right.

ACTUAL MODEL VIEW Approved screenshot from the integrated workbook. It shows the side-by-side actual-to-forecast structure used for review; sensitive names and identifiers were pre-sanitized per user direction.

> **Why it mattered:** a single row structure made monthly spikes, trend changes, distribution timing, and return sensitivity easier to inspect without forcing asset managers back into disconnected accounting and forecast files.

DRILL-DOWN CAPABILITY - ACCOUNTING DETAIL WITHOUT ROUTINE PULLS

The model retained transaction-level support behind the summary rows. Reviewers could move from a monthly NOI or capex variance to the underlying rows and focus first on the largest cash-flow drivers.

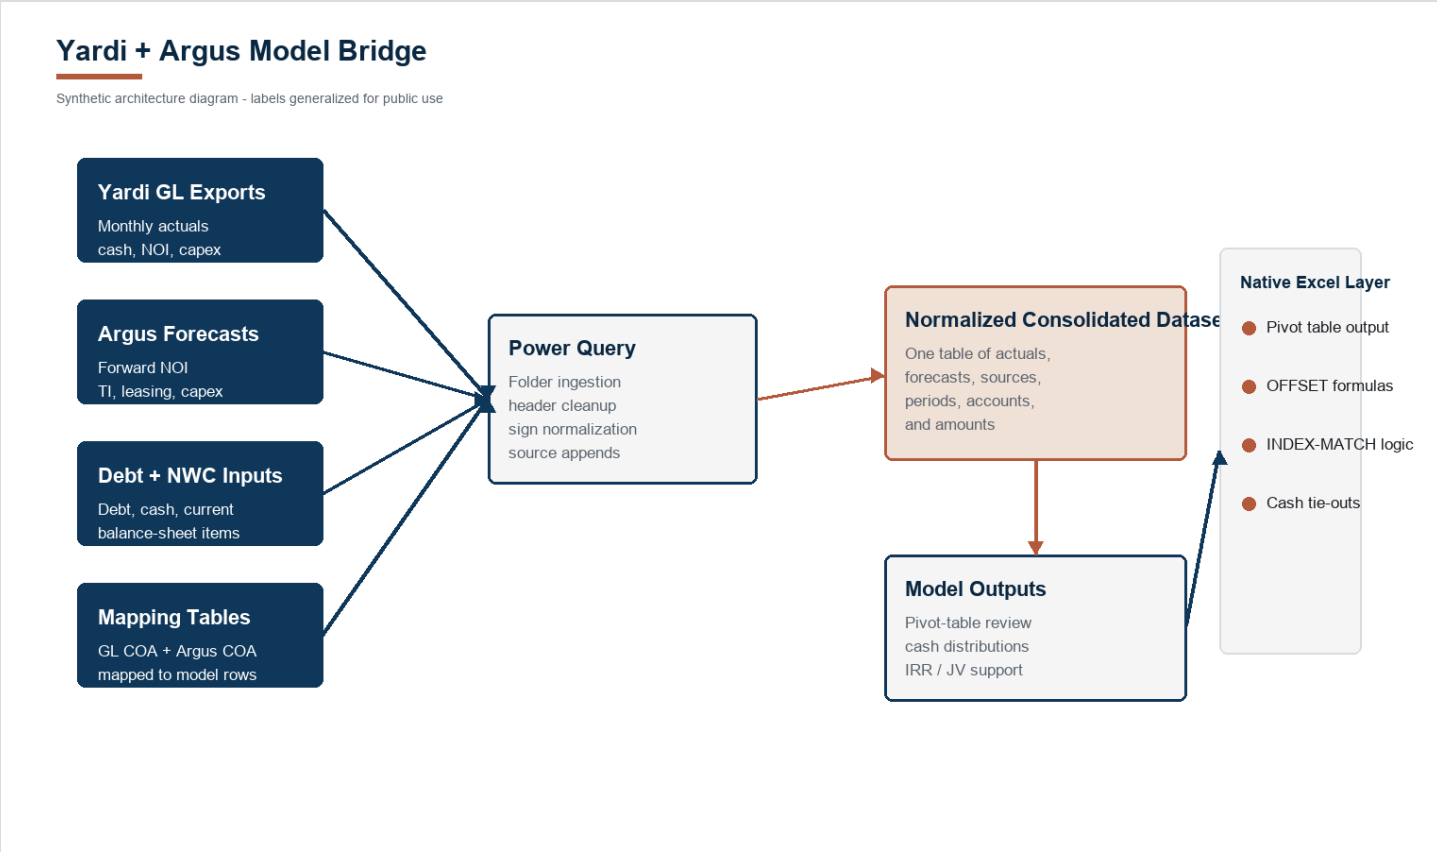
CAPEX DRILL-DOWN Actual workbook screenshot showing capex detail review. Full drill-down workbooks were used internally; investor-facing files used summarized outputs.

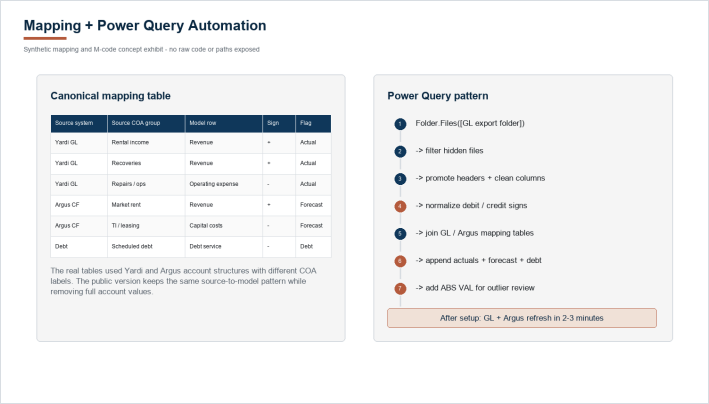
SYSTEM ARCHITECTURE - YARDI, ARGUS, MAPPING, MODEL

The architecture decision was the hard part: keep accounting actuals, forecast rows, debt, cash, mapping tables, and working-capital logic separate at the source, then normalize them into one consolidated dataset. That made the model reusable across properties and reduced the rebuild burden for new acquisitions.



ARCHITECTURE Synthetic architecture diagram. Yardi GL exports, Argus forecasts, debt and net working capital inputs, and mapping tables feed Power Query at the same level. Power Query creates the normalized consolidated dataset that supports model outputs, pivot-table review, and native Excel formulas.

TRANSFORMATION LOGIC



Mapping + Power Query Automation

Synthetic mapping and M-code concept exhibit - no raw code or paths exposed

Canonical mapping table

Source system	Source COA group	Model row	Sign	Flag
Yardi GL	Rental income	Revenue	+	Actual
Yardi GL	Recoveries	Revenue	+	Actual
Yardi GL	Repairs / ops	Operating expense	-	Actual
Argus CF	Market rent	Revenue	+	Forecast
Argus CF	TI / leasing	Capital costs	-	Forecast
Debt	Scheduled debt	Debt service	-	Debt

The real tables used Yardi and Argus account structures with different COA labels. The public version keeps the same source-to-model pattern while removing full account values.

Power Query pattern

1. Folder.Files([GL export folder])
2. -> filter hidden files
3. -> promote headers + clean columns
4. -> normalize debit / credit signs
5. -> join GL / Argus mapping tables
6. -> append actuals + forecast + debt
7. -> add ABS VAL for outlier review

After setup: GL + Argus refresh in 2-3 minutes

MAPPING Distilled synthetic mapping exhibit based on the GL and Argus COA table patterns. It preserves the logic shape without exposing full account values.

POWER QUERY HANDLED AFTER SETUP

- Folder-file ingestion made the update pattern simple: export the GL report, place it in the property folder, refresh.
- Header cleanup, column selection, debit-credit sign normalization, account mapping, and appended actual/forecast/debt rows ran through the query layer.
- Model outputs then fed pivot-table review, while cash distributions, contribution/distribution tracking, and other KPIs were tracked natively in Excel using OFFSET / INDEX-MATCH style formulas outside the pivot.
- A new GL-period and Argus-forecast refresh could take 2-3 minutes once the model was configured.

CONTROLS AND REFRESH PROCESS

The workflow was not a black box. Outputs were reviewed before internal decisions or external summaries. The strongest controls were cash tie-outs, T6 NOI checks, visible-period review, and variance troubleshooting driven by the transaction-level architecture.

Cash tie-out.
Cash in the model was manually compared to Yardi for the latest reporting period before the model was used.

T6 NOI tie-out.
Trailing-six NOI was checked against the latest reporting period to confirm the transformed actuals were behaving correctly.

Refresh sequencing.
Some models required refresh-all twice: once for queries and once for the pivot/data model. New period filters were reviewed if months did not immediately appear.

Human review.
Outputs were reviewed internally, then summarized for external JV reporting. Full drill-down workbooks were not shared externally because of GL-detail sensitivity.

CASH, NET WORKING CAPITAL, DISTRIBUTION LOGIC

Cash Distribution + NWC Logic

Synthetic decision-support exhibit - example figures rounded and generalized

Current cash	Minimum reserve	Working capital	Near-term capex	Debt service	Capacity
100	(42)	(27)	(18)	(13)	0
Tie to Yardi cash	Management threshold	AR/AP/prepaids/accruals	TI, leasing, capital	Scheduled payments	Distribution or call signal

Controls in the model

- Cash tie-out to Yardi before forecast use
- Balance-sheet NWC schedule by account group
- Period filter review after refresh
- Manual review before external summary

Decision-support example

~$800K

Q4 2025 capital-call reduction example vs. forward-only models, based on detailed cash and balance-sheet burn-down analysis. Sanitized and qualified as one decision-support example.

DECISION WORKFLOW Synthetic workflow exhibit showing the logic used before sizing distributions or capital calls.

```
DistributionCapacity =
  MAX(0,
      CurrentCash
    + PriorPeriodCashFlow
    - MinimumReserve
    - NearTermCapexAndLeasingCosts
    - ScheduledDebtService
    - NetWorkingCapitalBurnoff)
```

Pseudocode: start with current cash, add prior-period cash flow, hold back the minimum reserve, subtract near-term capital costs, scheduled debt service, and expected net working capital burn-off, then treat any positive residual as potential distribution capacity. In one Q4 2025 decision-support example, this balance-sheet-grounded view supported roughly $800K lower JV partner fund-level capital calls versus forward-only models.

FORMULA EVIDENCE - DYNAMIC CASH DISTRIBUTION LOGIC

The formula screenshot below is included as evidence of the workbook-level logic behind the decision workflow. The public explanation uses readable placeholders instead of raw cell references because the business logic matters more than exposing model coordinates.

AL38

```
=IF(AM$3<=$E$61,IF(AL6+INDEX($B$11:$EB$38,MATCH("CHANGE IN CASH",$B$11:$B$38,0),AM5+1)>$AM$48,AL6+
INDEX($B$11:$EB$38,MATCH("CHANGE IN CASH",$B$11:$B$38,0),AM5+1)-$AM$48,0),0)
```

FORMULA EVIDENCE Actual workbook screenshot showing dynamic distribution logic and the formula bar. The case-study formula above translates the same concept into readable business terms.

KNOWN IMPROVEMENT AREAS

The model was intentionally kept in use because the existing process was producing high-quality results, but the architecture had clear improvement areas. The original build reflected the tooling, timeline, and operating requirements at the time: refresh behavior could be cleaner, period filters could be more automated, and a modern rebuild could use a more formal data layer and AI-assisted documentation/testing around the same finance logic.

BUSINESS IMPACT - DETAIL

30

INVESTOR-FACING AM MODELS IN 12 MONTHS

- Rolled out investor-facing asset-management model coverage across 20 properties in 6 months and 30 properties in 12 months.
- Reduced the GL-period plus Argus-forecast refresh from roughly 80-90 minutes manually to roughly 2-3 minutes once configured.
- Allowed the most experienced model user to build a 6-12 month cash reforecast in roughly 10-15 minutes versus about 2.5 hours manually.
- Supported a Q4 2025 decision-support example that reduced JV partner fund-level capital calls by approximately $800K versus forward-only modeling.

QUALITATIVE IMPACT

- **Faster portfolio visibility:** recurring quarterly investor reporting started from a fuller actual-to-forecast model.
- **Better variance review:** side-by-side presentation and drill-down made spikes easier to spot and investigate.
- **Stronger forecast confidence:** IRR projections considered current cash, debt, and net working capital timing instead of relying on forward models alone.
- **Lower accounting dependency:** after update, standard accounting pulls were generally unnecessary unless the model surfaced a specific outlier.

TRANSFERABLE RELEVANCE

- **Finance systems judgment:** chose Excel and Power Query because they matched the users, source systems, and review workflow.
- **Accounting-to-FP&A bridge:** mapped GL accounts, Argus forecast rows, cash, debt, net working capital, and IRR logic into one usable model.
- **Automation readiness:** the same pattern applies anywhere standard GL exports must become structured decision data.
- **AI-workflow relevance:** because this was built pre-AI, it shows the underlying process architecture that can now be improved faster with current tools.

SANITIZATION AND SHARING BOUNDARY

This v2 artifact uses approved raw screenshots for selected model-output, drill-down, and formula exhibits per user direction. Synthetic exhibits are still used for architecture, mapping, and workflow logic. Company, property, tenant, lender, investor, URL, network-path, workbook-metadata, account-detail, and financial/model details should remain generalized where they are not already pre-sanitized.
